

1st EFLM Strategic Conference
Defining analytical performance goals
15 years after the Stockholm Conference
8th CIRME International Scientific Meeting

Performance Criteria for: The Post-analytical Phase

A/Prof Ken Sikaris
 Chemical Pathologist
 Melbourne Pathology, Australia
 BSc(Hons), MBBS, FRCPA, FFSc, FAACB, GAICD

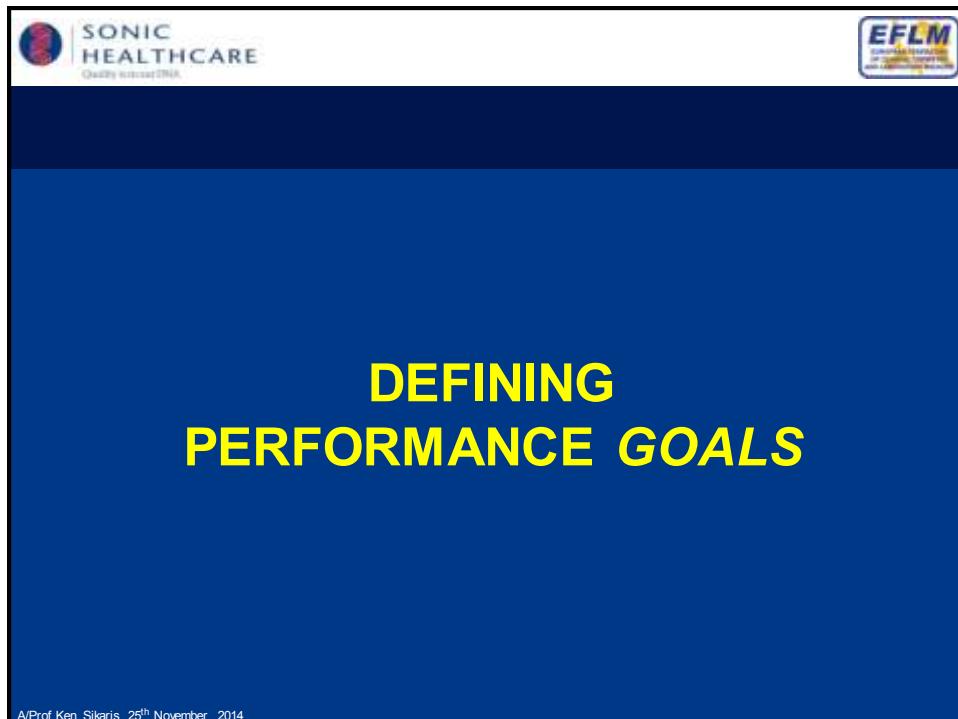

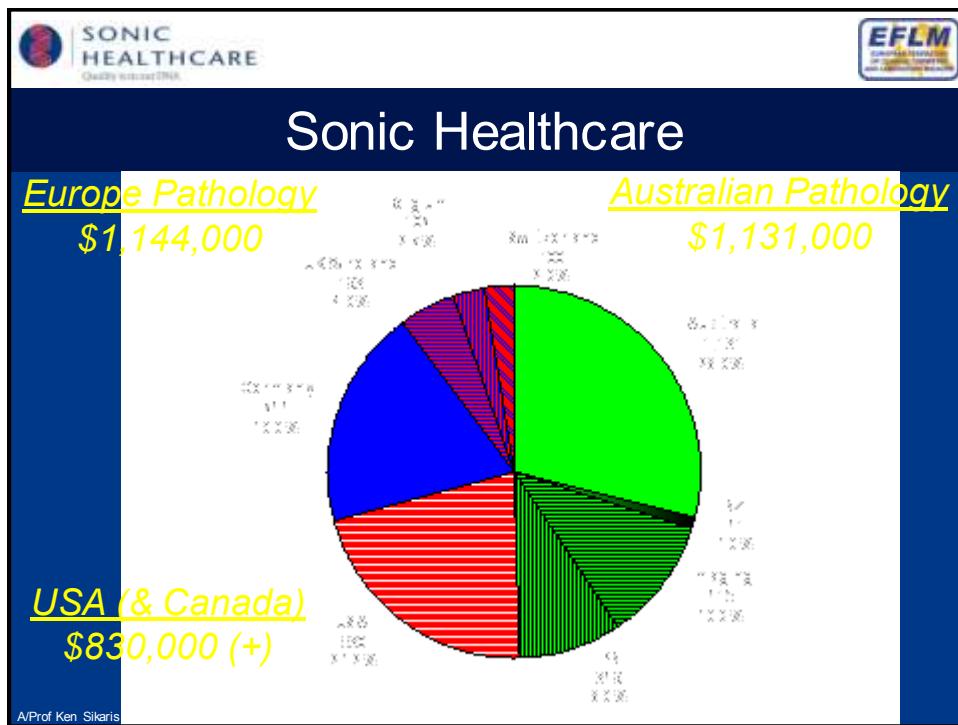

A/Prof Ken Sikaris 25th November 2014

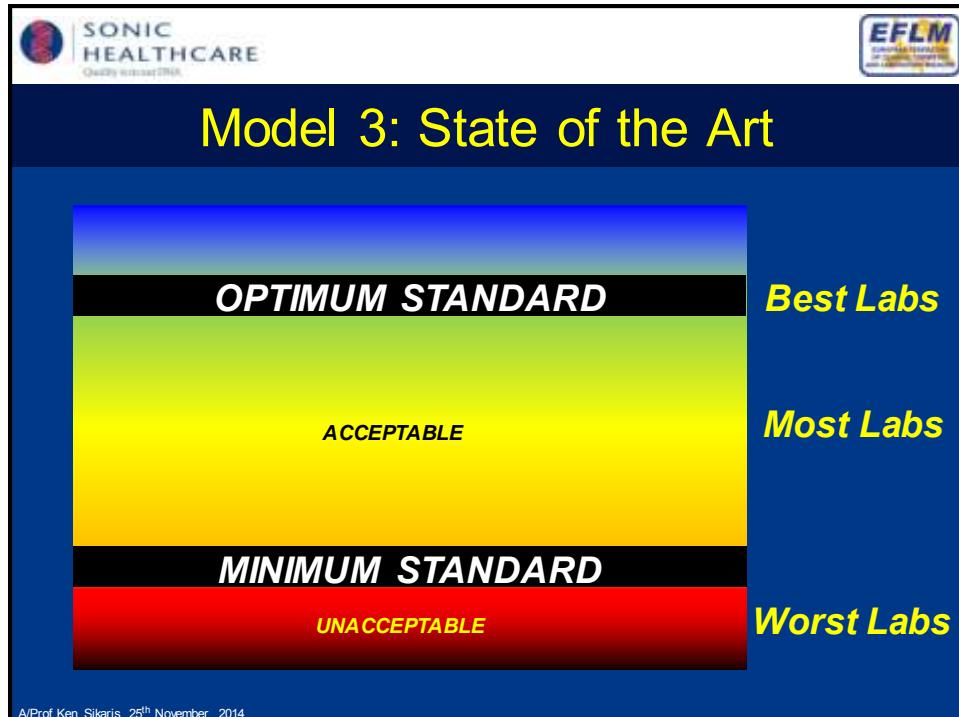

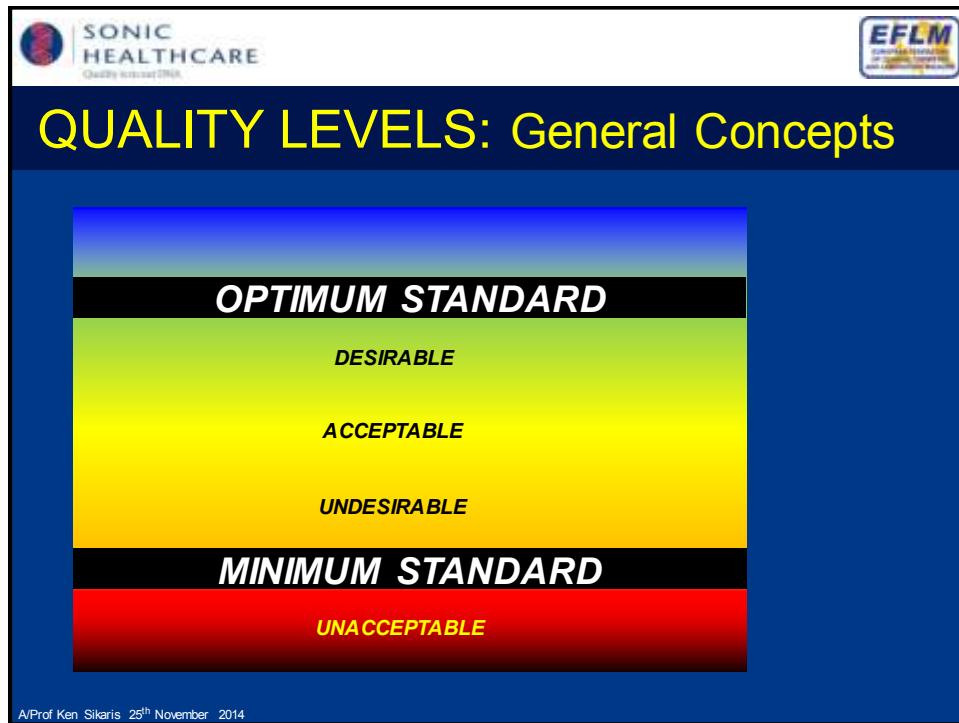

OUTLINE

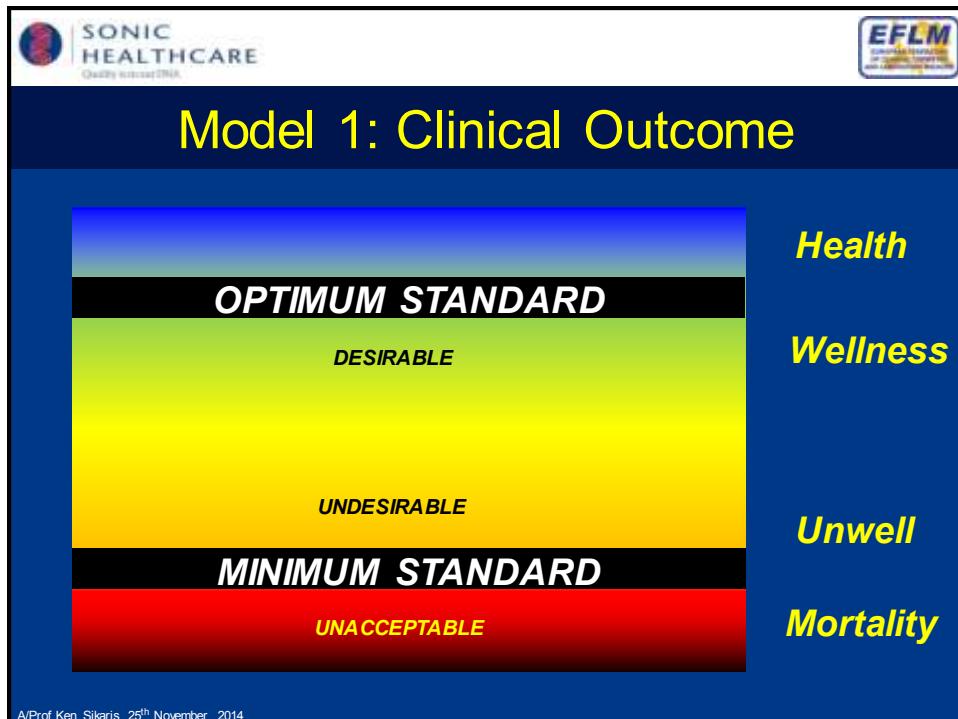

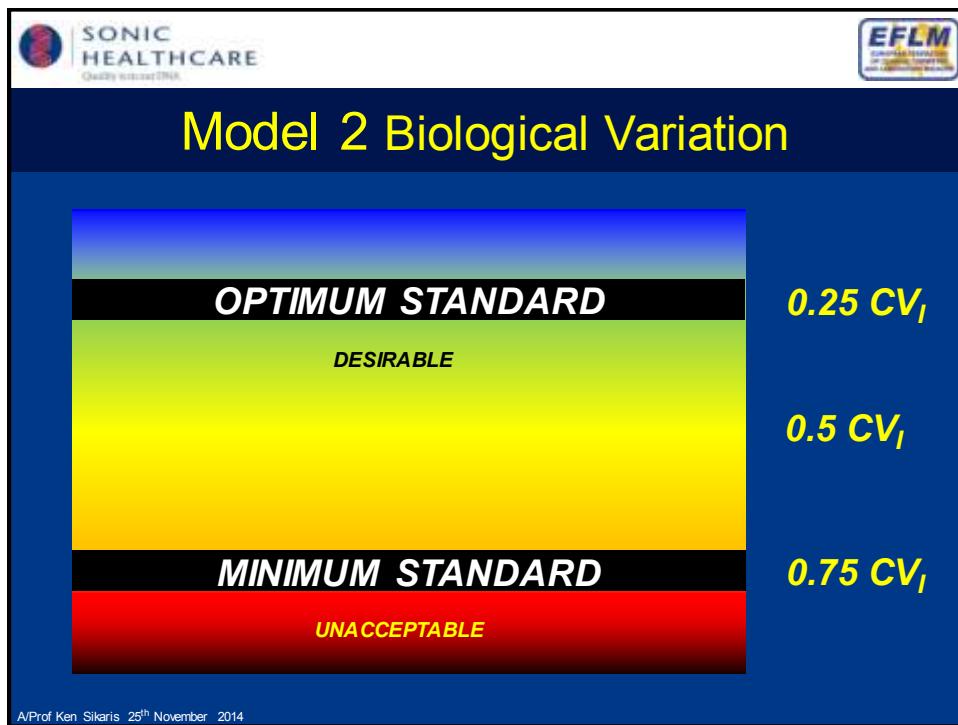

- Defining Performance Goals
 - Minimal / Desirable / Optimal
- Defining the Post-Analytical phase
 - Data, Information, Knowledge and Action
- Hierarchical Performance Criteria
 - Reference Intervals & Clinical Decision Limits
 - Significant Changes
 - Critical limits

A/Prof Ken Sikaris 25th November 2014

**SONIC
HEALTHCARE**
Quality since 1964

DEFINING THE POST-ANALYTICAL PHASE

Quality since 1964

“The Brain to Brain Loop”

A/Prof Ken Sikaris 25th November 2014

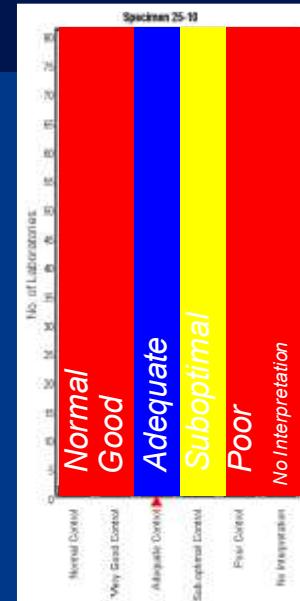

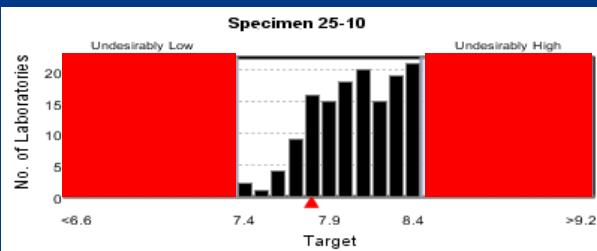

ISO17043 Appendix A1

- Three basic types of laboratory examinations
 - Quantitative measurement: interval or a ratio scale.
 - Qualitative tests: ordinal or categorical scale
 - Interpretive tests concerning participant's interpretive competence.

A/Prof Ken Sikaris 25th November 2014

Target HbA1c = 7.9%

Programs

Alcohol/Ammonia	For the analysis of alcohol and ammonia.
Basic Chemistry	Designed for very small laboratories doing a limited range of testing. Only available for laboratories outside Australia and New Zealand.
Point-of-Care Testing Programs designed specifically for point-of-care testing instruments.	
Options Chemistry	Troponin - Tni using the Abbott i-STAT & TnT using the Roche cobat h32.
Porphyrins	For the analysis of porphyrins, porphyrin components and patient report comments.
Options Plasma	Options Plasma

CHEM - INTERPRETIVE

Case 6 12-08-02

Patient ID 21 year old woman
Patient Location General Practitioner
Case Details
 Plasma:
 Glucose 9.2 mmol/L
Clinical Notes on Request Form
 Mid-trimester screening
Additional Information
 Sample taken one-hour post 75gm glucose load. Not a known diabetic.

A Suggested Comment
 Positive glucose challenge test. A full 2 hour 75gm glucose tolerance test is indicated.

Rationale and References
 Recommendations of the Australian Diabetes in Pregnancy Society (www.adips.org) were published in the Medical Journal of Australia and are referred to by the New Zealand Society for the Study of Diabetes (www.diabetes.org.nz). A glucose level of ≥ 10.0 at 1 hour after a 75gm load is a positive oral glucose challenge test and the patient should proceed to a full 2 hour OGTT for confirmation. It should also be noted that most women with a positive challenge do not turn out to have gestational diabetes.
 References: Hoffman L, et al Med J Aust 1998;168:93-97.

Performance Criteria:

- **Quantitative**

- Within acceptable performance for bias
- Within acceptable performance for imprecision

- **Categorical**

- If they are identical, then performance is acceptable.
- If they are not identical, then expert judgement is needed to determine if the result is fit for its intended use.

Quality Assessment of Interpretative Commenting in Clinical Chemistry

Ee Mun Lim,¹ Ken A. Sikaris,^{2,3} Janice Gill,³ John Calleja,³ Peter E. Hickman,⁴ John Beilby,^{1,5} and Samuel D. Vasikaran^{5,6*}

Conclusion: The golden rule in medicine is “do no harm”. Although there is no objective evidence that interpretive comments help to improve patient outcomes, if comments are added to reports it is important that they reflect accepted practice and current guidelines.

Quality of interpretative commenting on common clinical chemistry results in the Asia-Pacific region and Africa

Samuel D. Vasikaran^{1,2,*}, Leslie C. Lai³, Sunil Sethi⁴, Joseph B. Lopez⁵ and Kenneth A. Sikaris⁶

Conclusions: While interpretative commenting is an important laboratory activity, the results of this study suggest that there is room for improvement in the quality of interpretative comments offered by senior laboratory professionals, even for commonly reported results relating to most prevalent and important public health conditions.

and continuing professional development in this area is required for the provision of a quality interpretative service.

Provision of interpretative comments on biochemical report forms

William J Marshall¹ and Gordon S Challand²

SUMMARY. Providing interpretative comments on reports, particularly those for primary care physicians is an important part of our job. Few clinical biochemists (whether medical or scientific) receive significant training for this.

45 y/o man, PSA = 3.2 ug/L

Table 6 Examples of participant comments with designation of participant (D=Medical, S=Scientist) and mean score given by the Program Committee, together with the comment drafted by the Program Committee for case 3.

D/S	Mean score	Participants' comments
S	0	The PSA value is in normal range. It shows that patient is not having any malignancy prostate problem, but in this age group he should get it repeated every year for further safety, as this age group can have risk.
S	3.5	PSA value of 3.2 $\mu\text{g/L}$ cannot rule out prostatic cancer in this age group. Family history of prostate cancer, an abnormal DRE and results of previous prostate biopsy if any help assessment of cancer risk. PSA density and free-to-total PSA fraction ratio assays may further delineate risk level. Based on risk level and patient's understanding of the consequences of a cancer diagnosis, he can best determine whether urology referral for a prostate biopsy or expectant management [Truncated].

Comment drafted by the Program Committee

PSA, prostate specific antigen; DRE, digital rectal examination.

The image displays two journal covers side-by-side. On the left is 'The Scandinavian Journal of Clinical & Laboratory Investigation' (Volume 69, No. 2, November 1999). The cover features a blue background with the title in white serif font at the top, followed by a large photograph of a medical professional in a lab coat. Below the photo are several article titles and authors. On the right is 'EFLM' (European Federation of Clinical Chemistry and Laboratory Medicine) (Volume 10, No. 1, October 1999). This cover has a yellow header with the acronym 'EFLM' in large letters, followed by the journal name. It also features a large photograph of a medical professional. Both covers have a vertical column of text on the right side listing article titles and authors.

Hierarchy for Reference Intervals & Decision Limits

Table 2. The Stockholm Hierarchy applied to reference intervals and clinical decision limits.

1. Clinical decision limit based on clinical outcome study
e.g. HbA_{1c} cut-off based on the presence of diabetes outcome (retinopathy).¹⁸
2. Other methods of determining reference interval or clinical decision limit
 - a. Reference intervals derived from apparently healthy populations e.g. NORIP,²⁰ CALIPER.²¹
 - b. Clinical decision limits based on clinicians' opinions of disease e.g. thyroid-stimulating hormone (TSH) upper reference limit (2.5 mIU/L) from NACB.²²
3. Published professional recommendations
 - a. National or international expert bodies e.g. national urine protein cut-offs.²³
 - b. Expert local groups or individuals e.g. ARQAG,²⁴ SONIC.²⁵
4. Reference limits set by
 - a. Regulatory bodies e.g. prostate-specific antigen (PSA) cut-offs.²⁶
 - b. Formal Reference Interval Survey e.g. UK Harmony Survey.²⁷
5. Reference limits based on the current state of the art
 - a. Reference interval used in postanalytical external quality assurance e.g. pathology interpretation exercises.²⁸
 - b. Current publications on methodology e.g. textbooks or kit inserts.^{24,25}

Reference ranges in the real world

A Ellis

UK NEQAS for Peptide Hormones and Related Substances,
Department of Clinical Biochemistry, Royal Infirmary, Edinburgh
EH16 4SA.

In a recent survey of participants in the UK NEQAS for FSH and LH revealed that only 32% of laboratories had performed full in-house studies. The majority (52%) used data provided by the manufacturer of their current method whilst 16% relied on data from the scientific literature. In addition, some laboratories referred to historical data derived experimentally for assays no longer in use.

UK: FSH & LH

32% - In house
52% - Manufacturer
16% - Literature

10 Transference

As more new tests and methods are introduced in more laboratories, it is unrealistic to expect each laboratory, large and small, to develop its own reference intervals. Consequently, clinical laboratories may rely more and more on other laboratories or diagnostic test manufacturers to generate and provide appropriate and adequate reference value data that can be transferred.

Proposal for guidelines to establish common biological reference intervals in large geographical areas for biochemical quantities measured frequently in serum and plasma

Pål Rustad^{1,*}, Peter Felding² and Ari Lahti³

To introduce biological reference intervals, laboratories should verify that their measurement systems fulfill criteria for metrological quality such as metrological variation (s_M) and method bias (B). The following quality goals, based on the standard deviation of biological variation (s_B), have been suggested (20):

Goal for metrological variation: $s_M < s_B / 2$

Goals for method bias:

Optimum: $|B| < 0.125 \cdot s_B$
Desirable: $|B| < 0.250 \cdot s_B$
Minimum: $|B| < 0.375 \cdot s_B$

A/Prof Ken Sikaris 25th November 2014

Clin Chem Lab Med 2004;42(7):858-862

Analytical quality specifications for common reference intervals

Carmen Ricós^{1,*}, María Vicenta Doménech² and Carmen Perich³

From Gowans EM, Hyltoft Petersen P, Blaaberg O, Horder M, "Analytical goals for the acceptance of common reference intervals for laboratories throughout a geographical area." Scand J Clin Lab Invest. 1988 Dec;48(8):757-64.

Maximum imprecision (with no bias) of CV_A

$$<0.58 (CV_I^2 + CV_G^2)^{1/2}$$

Maximum bias (with no imprecision) of SE_A

$$<0.25 (CV_I^2 + CV_G^2)^{1/2},$$

A/Prof Ken Sikaris 25th November 2014

Reference Intervals & Biological Variability

- Ideally personalised limits
 - Reference intervals don't work if CV_I is very small
- Index of Individuality (II) = CV_I/ CV_G
 - Reference intervals most useful when $II<0.6$
 - Can be improved by limiting CV_G
 - Partition reference intervals (physiology)
 - Gender, Children, Adults, Pregnancy, Elderly

Australian reference intervals in healthy adults (ARIA) study

EFLM
European Federation
of Clinical Chemistry
and Laboratory Medicine

Introduction

Reference intervals are reference intervals for analytes determined by laboratory test results from a population of healthy individuals. These are often referred to as "Normal" ranges or "Healthy" ranges and are used to determine if a patient's test result is abnormal. In Australia, the National Health and Medical Research Council has developed guidelines for the determination of reference intervals for clinical chemistry analytes. The guidelines recommend that reference intervals be determined based on a population of healthy individuals. This study aims to establish Australian reference intervals for healthy adults using a large dataset of healthy individuals.

Materials and Methods

1000 volunteer samples were collected (450 males and 550 females) from healthy volunteers and investigated within 2 hours of collection. All samples were drawn after an overnight fast and collected immediately after venipuncture. The serum was separated and stored at -20°C until analysis. Up to 10 different analytical methods were used for each analyte. Data from the National Institute of Standards and Technology (NIST) Reference Materials were performed based on gender and age (Unadjusted). However, some parameters require data adjustment to account for reference interval differences and pathophysiology differences.

Results

Subject demographics are shown in Figure 1. The results of the study show that gender, age, and ethnicity have a significant impact on the reference intervals for most analytes. There are some differences seen in the results between the two genders, which also shows both gender and age differences unique to each gender. The newly determined reference intervals will be useful for improving consistency among and throughout the clinical laboratory testing process. (Source: ARIA, Sikaris 2014)

Table 1: Comparison between ARIA study with suggested AACB writing party reference intervals. 1007 (blue) = New Adult Diagnostic reference intervals for Male (140, female 100)

Total Protein	60 – 80 g/L	

A/Prof Ken Sikaris 25th November 2014

Primary role of reference intervals

- Initially use reference interval
 - We don't know what this patient's result should be
 - Compare this first result to similar people
- Subsequently use previous result as baseline
 - What is a significant change?

<i>Investigations: serum troponin measurement</i> Where available, high sensitivity troponin assays should be used in preference to conventional assays.	N/A
When using high sensitivity troponin assay, a test should be interpreted as positive if level is \geq 99th centile for reference population OR [redacted] above an initial baseline level.	Consensus
At 3 hours after presentation (with at least one assay performed >6 hours from symptom onset), a test using a high sensitivity troponin assay should be interpreted as negative if the level is <99th percentile AND change from baseline is <50%.	C

Post-analytical: Critical Limits

- Clinical Outcome
- Biological Variation
- State of the Art

A/Prof Ken Sikaris 25th November 2014

When to panic over an abnormal result.

George D Lundberg, Med Lab Obs 1972;

CRITICAL VALUES REPORTED IN ONE WEEK OF SEPTEMBER 1971			
TEST	Critical value	Critical limit	TESTS PERFORMED
Serum calcium	8	None	4,227
Serum potassium	13	22	4,173
Serum potassium-Norelco	None	1	4,173
Serum potassium-Homogenized specimen	None	1	4,173
Serum glucose	18	17	4,000
Serum glucose-Norelco	None	1	4,000
Serum calcium	None	None	108
Prothrombin activity	21	None	1,012
Arterial or capillary blood pH	23	None	378
Arterial or capillary blood PCO ₂	1	25	215
Arterial or capillary blood pH	23	None	378
Serum bicarbonate	13	16	4,095
Platlet count	1	None	176
Positive RBC culture	4	None	5,374
Blood hemoglobin	8	None	5,374
Positive blood culture (2)			832
Positive cerebrospinal fluid gram stain (2)			216

PANIC VALUES

A/Prof Ken Sikaris 25th November 2014

Survey of laboratory 'critical limits'.

Tillman & Barth Ann Clin Biochem 2003;40:181-184.

- No consensus in UK
 - All labs have common tests
 - Na, K, Glu, (Ca)
 - Wide variation in common tests
 - Na 147 – 170, K 5.5 – 7.0
 - Similar to previous US reports.
 - Universal standards could be agreed.

STANDARDISATION OF CRITICAL VALUES AND NOTIFICATION OF RESULTS

1. Clinical Outcome (c) Expert Opinions

ACKNOWLEDGEMENT
List of authors and those that assisted in drafting manuscripts or who otherwise helped in the compilation of existing. All authors have read and approved the final version of the manuscript. The authors declare that they have no conflicts of interest. This article is the result of a joint EFLM-SONIC Healthcare Association discussion on a problem in clinical laboratory medicine, and it reflects the views of the authors.

INTRODUCTION
Critical values and critical limits are widely used in clinical laboratories to indicate the values at which urgent action must be taken to prevent serious adverse events. The term 'critical value' is often used interchangeably with 'critical limit'. Critical values are usually defined as values above which immediate patient management is required to prevent serious adverse events. Critical limits are the values above which immediate patient management is required to prevent serious adverse events. Critical values are commonly determined by medical committees and critical limits are usually determined by laboratory committees.

CONCLUSION
The survey results support the notion that there is a significant variation in critical values and critical limits between laboratories. Further, there is a lack of consensus among experts on what constitutes a critical value and how it should be communicated to the clinician.

ACKNOWLEDGEMENT
The authors acknowledge the efforts of a number of pathologists and clinicians in the clinical chemistry department of the University of Western Ontario (London, Ontario, Canada) who contributed to this work.

RELATIONSHIP BETWEEN REFERENCE INTERVALS AND MORTALITY-BASED REFERENCE RANGES

K. Sikaris, A. Martin and MD Guerin
Department of Chemical Pathology, Alfred Hospital, Private Bag No. 7, Melbourne West, Vic. 3001.

There have been many attempts to define health ranges for clinical laboratory analyses, including normal ranges and reference ranges. There have been even attempts, however, to link changes in analyte levels in healthy individuals with clinical outcome events. Clinical outcome levels, however, may be linked with mortality associated with a pathophysiological range for several reasons:

- A 24-month rate of mortal mortality and the currently accepted reference ranges for several common analytes.
- The applicable information from the literature is often incomplete or conflicting. There are three main health ranges that often the particular analytes agree very closely, particularly with respect to most electrolytes. The relationship with plasma bicarbonate may indicate the "protective" effect of metabolic alkalosis in cases of chronic kidney disease.
- With respect to other analytes, for example urate, the mortality ranges are much wider and less reliable. This suggests that the clinically "acceptable window" may be more tolerant of hyperuricemia. Consequently, clinicians interested in preventing mortality would not need to respond to elevations in plasma urate until levels were much higher than those indicated by reference intervals. In other situations, mortality rates may, of course, be associated with increasing mortality regardless of the analyte measured, if the primary effect of the condition is, again, mortality-based ranges may be of significant clinical value in alerting clinicians to life-threatening complications of disease processes.

* Mortality
** Critical

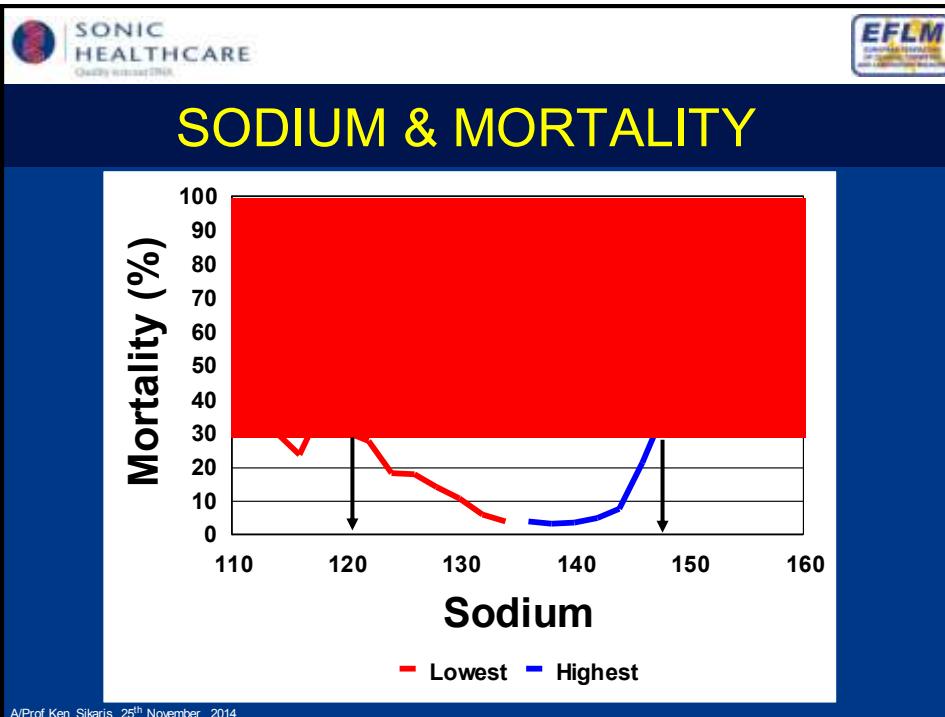

The applicable information from the literature is often incomplete or conflicting. There are three main health ranges that often the particular analytes agree very closely, particularly with respect to most electrolytes. The relationship with plasma bicarbonate may indicate the "protective" effect of metabolic alkalosis in cases of chronic kidney disease.

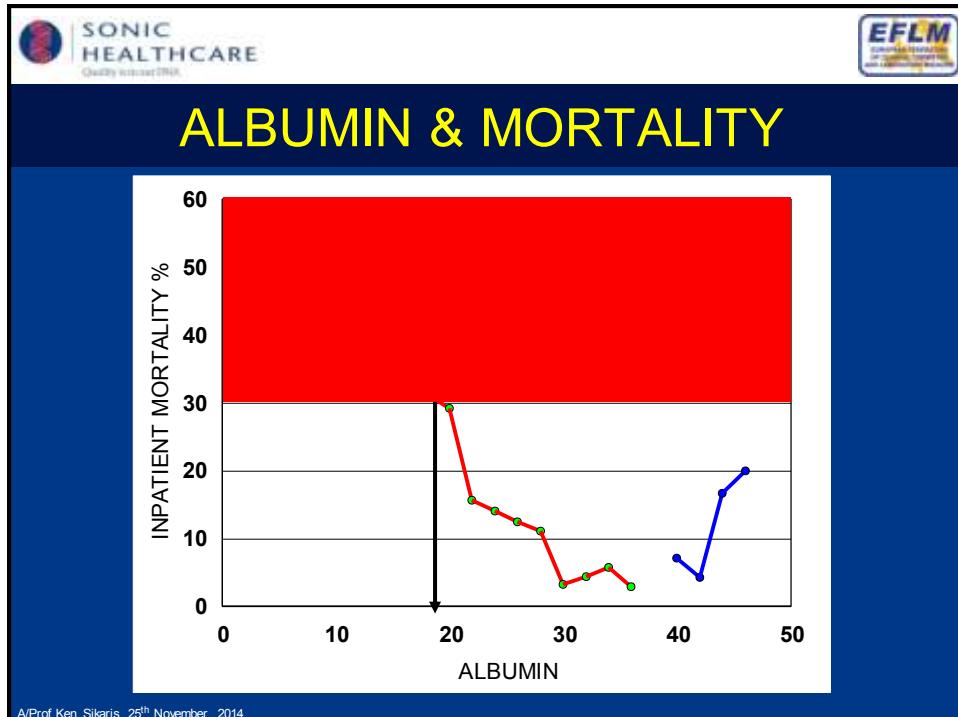

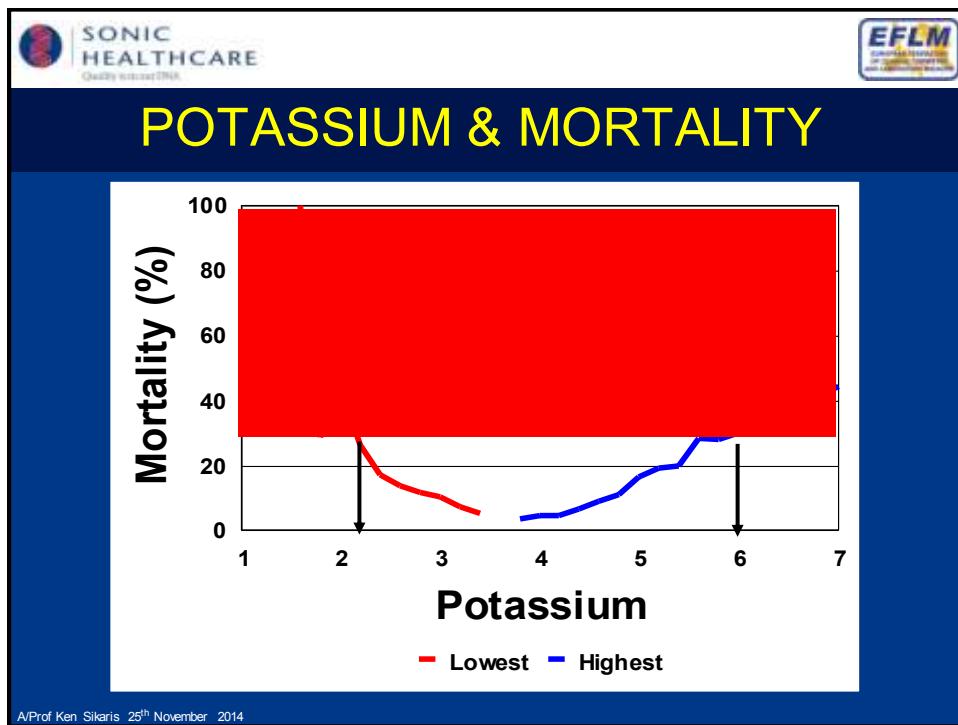

* Mortality range is determined by a doubling of mortality over the baseline level.
 ** Critical range is determined by a 25% mortality rate associated with that analyte level.

Analyte	Reference Range	Mortality Range*	Critical Range**
Sodium	136-145	133-144	123-148
Potassium	3.5-4.5	3.3-4.6	2.3-5.6
Bicarbonate	22-30	23-36	17-42
Urate	0.2-0.45	>0.79	>0.89
Calcium	2.13-2.63	2.19-2.75	1.89-2.85
Albumin	36-48	<31	<21

A/Prof Ken Sikaris 25th November 2014

1. Clinical Outcome (a) Outcome

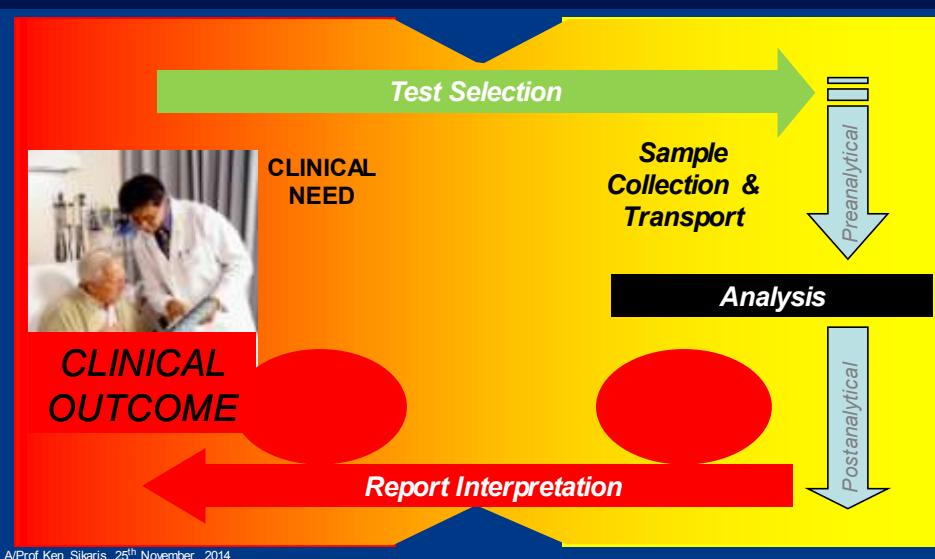

Survey of laboratory 'critical limits'.

Tillman & Barth Ann Clin Biochem 2003;40:181-184.

- Do clinicians respond?
 - Ca⁺⁺
 - >3.0 mmol/L:
 - immediate change in management
 - Albumin
 - Never changes management
 - (8 labs quote a critical limit)
